

Package ‘restriktor’

December 19, 2024

Title Restricted Statistical Estimation and Inference for Linear Models

Version 0.6-10

Description Allow for easy-to-use testing or evaluating of linear equality and inequality restrictions about parameters and effects in (generalized) linear statistical models.

Depends R(>= 4.0.0)

Imports boot, lavaan(>= 0.6-10), MASS, mvtnorm, tmvtnorm, quadprog, norm, ggplot2, future, future.apply, progressr, scales, gridExtra

License GPL (>= 2)

LazyData yes

restriktor-package	<i>Package for equality and inequality restricted estimation, model selection and hypothesis testing</i>
--------------------	--

Description

Package restriktor implements estimation, testing and evaluating of linear equality and inequality restrictions about parameters and effects for univariate and multivariate normal models and generalized linear models.

Details

Package:	restriktor
Type:	Package
Version:	0.6-10
Date:	2024-12-19
License:	GPL (>=2)
LazyLoad:	yes

Function restriktor estimates the parameters of an univariate and multivariate linear model (`lm`), robust estimation of the linear model (`r1m`) or a generalized linear model (`glm`) subject to linear

equality and/or inequality restrictions. The real work horses are the `conLM`, `conMLM`, the `conRLM`, and the `conGLM` functions. A major advantage of **restriktor** is that the constraints can be specified by a text-based description. This means that users do not have to specify the complex constraint matrix (comparable with a contrast matrix) themselves.

The function `restriktor` offers the possibility to compute (model robust) standard errors under the restrictions. The parameter estimates can also be bootstrapped, where bootstrapped standard errors and confidence intervals are available via the summary function. Moreover, the function computes the Generalized Order-restricted Information Criterion (GORIC), which is a modification of the AIC and a generalization of the ORIC.

The function `iht` (alias `conTest`) conducts restricted hypothesis tests. F, Wald/LRT and score test-statistics are available. The null-distribution of these test-statistics takes the form of a mixture of F-distributions. The mixing weights (a.k.a. chi-bar-square weights or level probabilities) can be computed using the multivariate normal distribution function with additional Monte Carlo steps or via a simulation approach. Bootstrap methods are available to calculate the mixing weights and to compute the p-value directly. Parameters estimates under the null- and alternative-hypothesis are available from the summary function.

The function `goric` (generalized order-restricted information criterion) computes GORIC values, weights and relative-weights or GORICA (generalized order-restricted information criterion approximation) values, weights and relative weights. The GORIC(A) values are comparable to the AIC values. The function offers the possibility to evaluate an order-restricted hypothesis against its complement, the unconstrained hypothesis or against a set of hypotheses. For now, only one order-restricted hypothesis can be evaluated against its complement but work is in progress to evaluate a set of order-restricted hypothesis against its complement.

The package makes use of various other R packages: **quadprog** is used for restricted estimation, **boot** for bootstrapping, **ic.infer** for computing the mixing weights based on the multivariate normal distribution, **lavaan** for parsing the constraint syntax.

Value

The output of function `restriktor` belongs to S3 class `conLM`, `conMLM`, `conRLM` or `conGLM`.

The output of function `conTest` belongs to S3 class `conTest`.

These classes offer print and summary methods.

Acknowledgements

This package uses as an internal function the function `nchoosek` from **ic.infer**, which is originally from **vsn**, authored by Wolfgang Huber, available under LGPL.

The output style of the `iht` print function is strongly inspired on the summary of the `ic.test` function from the **ic.infer** package.

AngerManagement *Reduction of aggression levels Dataset (4 treatment groups)*

Description

The anger management dataset consists of reduction of aggression levels between week 1 (intake) and week 8 (end of training) from four different treatment groups (No-exercises, Physical-exercises, Behavioral-exercises, combination of physical and behavioral exercises).

Usage

```
data(AngerManagement)
```

Format

A data frame of 40 observations of 4 treatment variables and covariate age.

Anger reduction in aggression levels

Group No, Physical, Behavioral, Both

Age persons' age

benchmark_functions *Benchmark Functions for GORIC(A) Analysis*

Description

The 'benchmark' functions perform benchmarking for models using the Generalized Order-Restricted Information Criterion (Approximation) (GORIC(A)).

Usage

```

benchmark(object, model_type = c("asypm", "means"), ...)

benchmark_means(object, pop_es = NULL, ratio_pop_means = NULL,
  group_size = NULL, alt_group_size = NULL,
  quant = NULL, iter = 1000,
  control = list(),
  ncpus = 1, seed = NULL, ...)

benchmark_asypm(object, pop_est = NULL, sample_size = NULL,
  alt_sample_size = NULL, quant = NULL, iter = 1000,
  control = list(),
  ncpus = 1, seed = NULL, ...)

## S3 method for class 'benchmark'
print(x, output_type = c("rgw", "gw", "rlw", "ld", "all"),
  hypo_rate_threshold = 1, color = TRUE, ...)

## S3 method for class 'benchmark'
plot(x, output_type = c("rgw", "rlw", "gw", "ld"),
  percentiles = NULL, x_lim = c(), log_scale = FALSE,
  alpha = 0.50, nrow_grid = NULL, ncol_grid = 1,
  distr_grid = FALSE, ...)

```

Arguments

<code>object</code>	An object of class <code>con_goric</code> (a GORIC(A) object from the <code>goric</code> function).
<code>model_type</code>	If "means", the model parameters reflect (adjusted) means, else <code>model_type = "asypm"</code> (default). See details for more information about <code>asypm</code> .
<code>x</code>	An object of class <code>benchmark</code> or <code>benchmark</code> .
<code>pop_es</code>	A scalar or a vector of population Cohen's f (effect-size) values. By default, it benchmarks $ES = 0$ (no-effect) and the observed Cohen's f .
<code>pop_est</code>	A $1 \times k$ vector or an $n \times k$ matrix of population estimates to benchmark. By default, all estimates are set to zero (no-effect) and the observed estimates from the sample are used.
<code>ratio_pop_means</code>	A $1 \times k$ vector denoting the relative difference between the k group means. Note that a ratio of <code>c(3, 2, 1)</code> gives the same as <code>c(1, 0, -1)</code> , as the consecutive relative differences are 1 in both ratios. By default, the relative differences from the data are used.
<code>group_size</code>	If the GORICA object is based on estimates and their covariance matrix (instead of on a model/fit object), this should be a $1 \times k$ vector or a scalar to denote the group sizes. If a scalar is specified, it is assumed that each group is of that size.
<code>alt_group_size</code>	An $1 \times k$ vector or a scalar to denote alternative group sizes, if you want to use sizes different from those in the data. This can be used, for example, to see the values to which the GORIC(A) weights will converge (and thus to see the

	maximum value of the weights). If a scalar is specified, it is assumed that each group is of that size. By default, the group sizes from the data are used.
sample_size	A scalar to denote the (total) sample sizes. Only used if the GORIC object is based on estimates and their covariance matrix (instead of on a model/fit object) or alt_sample_size is not NULL.
alt_sample_size	A scalar to denote an alternative sample size if you want to use a different sample size from the one in the data. This can be used, for example, to see the values to which the GORIC(A) weights will converge (and thus to see the maximum value of the weights).
quant	Quantiles for benchmarking results. Defaults 5%, 35%, 50%, 65%, 95%.
iter	The number of iterations for benchmarking. Defaults to 1000.
hypo_rate_threshold	A numeric value specifying the threshold for the hypothesis rate. The function calculates the proportion of ratio-of-goric-weights that exceeds this threshold. Defaults to 1.
control	A list of control parameters. For more information, see details goric .
ncpus	Number of CPUs to use for parallel processing. Defaults to 1. See details for more information.
seed	A seed for random number generation.
output_type	A character vector specifying the type of output to print or plot. Options are "all", "gw" (goric(a) weights), "rgw" (ratio of goric(a) weights), "rlw" (ratio of log-likelihood values), and "ld" (log-likelihood difference). Defaults to "rgw" for print and "rgw" for plot.
color	If TRUE, the output will include ANSI color coding. Set color = FALSE when using this function in R Markdown documents to avoid rendering issues with color codes.
alpha	Alpha refers to the opacity of a geom. Values of alpha range from 0 to 1, with lower values corresponding to more transparent colors.
nrow_grid	An integer value representing the number of rows in the grid layout.
ncol_grid	An integer value representing the number of columns in the grid layout.
distr_grid	If TRUE, the facet_grid function is used to create a grid of separate plots for each effect-size (estimates).
percentiles	A numeric vector specifying the percentiles to be shown. By default the percentiles are inherited from the quantiles used for benchmarking, see quant.
x_lim	A numeric vector of length 2 specifying the x-axis limits. Defaults to c().
log_scale	logical, If TRUE, The x-axis is transformed using a base-10 logarithmic scale. This transformation adjusts the way the data is visualized on the x-axis, but does not alter the underlying data values themselves.
...	See goric .

Details

The function `benchmark_asymp` is named as such because it generates data from a multivariate normal distribution with means equal to the population parameter estimates and a covariance matrix derived from the original data. This is based on the assumption that parameter estimates are asymptotically normally distributed. This assumption is valid for many statistical models, including parameters from a generalized linear model (GLM). In such models, as the sample size increases, the distribution of the parameter estimates tends to a normal distribution, allowing us to utilize the multivariate normal distribution for benchmarking.

`benchmark_means` benchmarks the group means of a given GORIC(A) object by evaluating various population effect sizes and comparing the observed group means against these benchmarks. `benchmark_asymp` benchmarks the population estimates of a given GORIC(A) object by evaluating various population estimates and comparing them against the observed estimates.

`print.benchmark` prints the results of benchmark analyses performed on objects of class `benchmark`.

`plot.benchmark` generates density plots for benchmark analyses of objects of class `benchmark`.

The `benchmark` function leverages the **future** package for parallel processing, allowing users to speed up computations by distributing tasks across multiple cores or machines. If the user does not specify a parallelization plan using `future::plan()`, the package will choose an appropriate strategy based on the user's operating system. Specifically, on Windows, the package defaults to using `multisession`, which creates separate R sessions for each parallel task. On Unix-like systems (such as Linux and macOS), the package defaults to `multicore`, which uses forked R processes to avoid the overhead of setting up separate R sessions.

The `plan()` must be specified before running the `benchmark` function, e.g., `future::plan(future::multisession, workers = ncpus)`

Value

`benchmark_means` and `benchmark_asymp` return a list of class `benchmark_means`, `benchmark`, and `list` or `benchmark_asymp`, `benchmark`, and `list` containing the results of the benchmark analysis.

`print.benchmark` does not return a value. It prints formatted benchmark analysis results to the console.

`plot.benchmark` returns a `gtable` object that can be displayed or further customized using various functions from the `gridExtra` and `grid` packages. This allows for flexible and detailed adjustments to the appearance and layout of the plot.

Examples

```
set.seed(1234)
# Generate data for 4 groups with different group sizes
group1 <- rnorm(10, mean = 5, sd = 0.1)
group2 <- rnorm(20, mean = 5.5, sd = 1)
group3 <- rnorm(30, mean = 6, sd = 0.5)
group4 <- rnorm(40, mean = 6.5, sd = 0.8)
```

```
# Combine data into a data frame
data <- data.frame(
  value = c(group1, group2, group3, group4),
  group = factor(rep(1:4, times = c(10,20,30,40)))
)

# Perform ANOVA
anova_result <- aov(value ~ -1 + group, data = data)

# model/hypothesis
h1 <- 'group1 < group2 < group3 < group4'
h2 <- 'group1 > group2 < group3 < group4'

# fit h1 and h2 model against the unconstrained model (i.e., failsafe to avoid
# selecting a weak hypothesis)
fit_goric <- goric(anova_result, hypotheses = list(H1 = h1, H2 = h2),
  comparison = "unconstrained", type = "goric")

# by default: ES = 0 \& ES = observed ES
# In practice you want to increase the number of iterations (default = 1000).

# multisession supports windows machines
# future::plan(future::multisession, workers = ncpus)
benchmark_results_mean <- benchmark(fit_goric, iter = 10, model_type = "means")
print(benchmark_results_mean)

# by default the ratio of GORIC weights for the preferred hypothesis (here h1) is
# plotted against its competitors (i.e., h2 and the unconstrained). To improve
# the readability of the plot, the argument hypothesis_comparison can be used to
# focus on a specif competitor. Further readability can be achieved by setting
# the x_lim option.
plot(benchmark_results_mean, output_type = "rgw")

# specify custom effect-sizes
benchmark_results_mean_es <- benchmark(fit_goric, iter = 10,
  pop_es = c(0, 0.1),
  model_type = "means")
print(benchmark_results_mean_es)

# Benchmark asymptotic estimates
fit_gorica <- goric(anova_result, hypotheses = list(h1=h1),
  comparison = "complement", type = "gorica")

# by default: no-effect \& estimates from the sample are used
benchmark_results_asymp <- benchmark(fit_gorica, sample_size = 30, iter = 5,
  model_type = "asymp")
print(benchmark_results_asymp)
```

```
# specify custom population estimates
my_pop_est <- rbind("no" = c(0,0,0,0), "observed"= coef(anova_result))

benchmark_results_asymp <- benchmark(fit_gorica, sample_size = 30,
                                     iter = 5, pop_est = my_pop_est,
                                     model_type = "asymp")

print(benchmark_results_asymp)
plot(benchmark_results_asymp, x_lim = c(0, 75))
```

bootstrapD

Bootstrapping a Lavaan Model

Description

Bootstrap the D statistic.

Usage

```
bootstrapD(h0 = NULL, h1 = NULL, constraints, type = "A",
           bootstrap.type = "bollen.stine", R = 1000L,
           return.D = FALSE, double.bootstrap = "no",
           double.bootstrap.R = 500L, double.bootstrap.alpha = 0.05,
           verbose = FALSE, warn = -1L,
           parallel = c("no", "multicore", "snow"), ncpus = 1L, cl = NULL,
           seed = NULL)

## S3 method for class 'conTestLavaan'
print(x, digits = max(3, getOption("digits") - 2), ...)
```

Arguments

h0	An object of class lavaan. The restricted model.
h1	An object of class lavaan. The unrestricted model.
x	an object of class conTestLavaan.
constraints	The imposed (in)equality constraints on the model.
type	hypothesis test type "A", "B".
bootstrap.type	If "parametric", the parametric bootstrap is used. If "bollen.stine", the semi-nonparametric Bollen-Stine bootstrap is used. The default is set to "bollen.stine".
R	Integer. The number of bootstrap draws.
return.D	Logical; if TRUE, the function returns bootstrapped D-values.

double.bootstrap	If "standard" (default) the genuine double bootstrap is used to compute an additional set of plug-in p-values for each bootstrap sample. If "no", no double bootstrap is used. If "FDB", the fast double bootstrap is used to compute second level LRT-values for each bootstrap sample. Note that the "FDB" is experimental and should not be used by inexperienced users.
double.bootstrap.R	Integer; number of double bootstrap draws. The default value is set to 249.
double.bootstrap.alpha	The significance level to compute the adjusted alpha based on the plugin p-values. Only used if double.bootstrap = "standard". The default value is set to 0.05.
verbose	If TRUE, show information for each bootstrap draw.
warn	Sets the handling of warning messages. See options .
parallel	The type of parallel operation to be used (if any). If missing, the default is "no".
ncpus	Integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
cl	An optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the bootstrapLavaan or bootstrapLRT call.
digits	the number of significant digits to use when printing.
...	no additional arguments for now.
seed	An integer to set the seed. Or NULL if no reproducible seeds are needed.

Value

A bootstrap p value, calculated as the proportion of bootstrap samples with a D statistic at least as large as the D statistic for the original data.

example2

```

Burns

Relation between the response variable PTSS and gender, age, TBSA, guilt and anger.

Description

Simulated dataset based on the original model parameters. The original data are based on two cohort studies in children from 0 to 4 and 8 to 18 years old with burns and their mother.

Usage

```
data(Burns)
```

Format

A data frame of 278 observations of 4 variables.

PTSS post-traumatic stress symptoms

gender gender

age age in years

TBSA estimated percentage total body surface area affected by second and third degree burns

guilt parental guilt feelings in relation to the burn event

anger parental anger feelings in relation to the burn event

References

Bakker A, Van der Heijden PG, Van Son MJ, Van Loey NE. Course of traumatic stress reactions in couples after a burn event to their young child. *Health Psychology* 2013; 10(32):1076-1083, doi:10.1037/a0033983.

Child and adolescent internalizing and externalizing problems 12 months postburn: the potential role of preburn functioning, parental posttraumatic stress, and informant bias. *Child and Adolescent Psychiatry* 2016; 25:791-803.

Examples

```
head(Burns)
```

```
calculate_IC_weights  Calculating IC weights based on IC values (AIC, ORIC, GORIC(A),
                      BIC, SIC, ...)
```

Description

This function transforms IC values into IC weights: IC values denote the ordering of hypotheses/models, while IC weights quantify the relative strength of hypotheses/models.

Usage

```
calculate_IC_weights(IC, hypo_names = NULL, use_scientific = TRUE)
calc_ICweights(IC, hypo_names = NULL, use_scientific = TRUE)

## S3 method for class 'goric_ICw'
print(x, digits = max(3, getOption("digits") - 4), ...)
```

Arguments

IC	A vector or one-column matrix with information criteria (AIC, ORIC, GORIC(A), BIC, SIC, ...) values of length 'NrHypos', where 'NrHypos' stands for the number of hypotheses/ models.
x	an object of class con_goric.
hypo_names	Optional. Vector containing 'NrHypos' characters which will be used for labeling the hypothesis. Default: H1, H2, ...
use_scientific	If TRUE (default), the IC weights and ratio of IC weights will be formatted using scientific notation. If FALSE, standard numeric formatting is used.
digits	the number of significant digits to use when printing.
...	no additional arguments for now.

Value

IC weights, which quantify the relative strength of hypotheses/models.

Examples

```
IC <- c(1,2,3)
calculate_IC_weights(IC)

## PT weights
# This examples shows how to calculate PT weights.
```

```

# Notably, one is interested in PT weights when the log-likelihood for two or more
# hypotheses are (approximately) equal.
# Then, the comparison between those hypotheses is solely based on the PT values.
# The IC weights will then equal the PT weights.
# In that case, there is support for the overlap (boundary) of these hypotheses.
# Thus, when the IC weights equal the PT weights for a (sub)set of hypotheses,
# then there is support for the overlap (boundary) of these hypotheses.

y <- rnorm(30)
group <- factor(rep(c("A","B","C"), each = 10))
fit.lm <- lm(y ~ -1 + group)
est <- coef(fit.lm)
VCOV_est <- vcov(fit.lm)
H1 <- "groupA < groupB < groupC"
results <- goric(est, VCOV = VCOV_est, hypotheses = list(H1),
                 comparison = "complement", type = "gorica")
calculate_IC_weights(results$result[,3])

```

conTestC

one-sided t-test for iht

Description

conTestC tests linear inequality restricted hypotheses for (robust) linear models by a one-sided t-test. This method is based on the union-intersection principle. It is called by the conTest function if all restrictions are equalities. For more information see details.

Usage

```

## S3 method for class 'restriktor'
conTestC(object, ...)

```

Arguments

```

object      an object of class restriktor.
...         no additional arguments for now.

```

Details

Hypothesis test Type C:

- Test H0: at least one restriction false (" $<$ ") against HA: all constraints strictly true (" $>$ "). This test is based on the intersection-union principle. Note that, this test only makes sense in case of no equality constraints.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequality constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

Value

An object of class `conTest`, for which a `print` is available. More specifically, it is a list with the following items:

<code>CON</code>	a list with useful information about the constraints.
<code>Amat</code>	constraints matrix.
<code>bvec</code>	vector of right-hand side elements.
<code>meq</code>	number of equality constraints.
<code>test</code>	same as input.
<code>Ts</code>	test-statistic value.
<code>df.residual</code>	the residual degrees of freedom.
<code>pvalue</code>	tail probability for <code>Ts</code> .
<code>b.unrestr</code>	unrestricted regression coefficients.
<code>b.restr</code>	restricted regression coefficients.
<code>Sigma</code>	variance-covariance matrix of unrestricted model.
<code>R2.org</code>	unrestricted R-squared.
<code>R2.reduced</code>	restricted R-squared.
<code>boot</code>	"no", not used (yet).
<code>model.org</code>	original model.

conTestF

F-bar test for iht

Description

conTestF tests linear equality and/or inequality restricted hypotheses for linear models by F-tests. It can be used directly and is called by the conTest function if test = "F".

Usage

```

## S3 method for class 'conLM'
conTestF(object, type = "A", neq.alt = 0,
         boot = "no", R = 9999, p.distr = rnorm,
         parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
         verbose = FALSE, control = NULL, ...)

## S3 method for class 'conRLM'
conTestF(object, type = "A", neq.alt = 0,
         boot = "no", R = 9999, p.distr = rnorm,
         parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
         verbose = FALSE, control = NULL, ...)

```

```
## S3 method for class 'conGLM'
conTestF(object, type = "A", neq.alt = 0,
         boot = "no", R = 9999, p.distr = rnorm,
         parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
         verbose = FALSE, control = NULL, ...)
```

Arguments

object	an object of class conLM, conRLM or conGLM.
type	hypothesis test type "A", "B", "C", "global", or "summary" (default). See details for more information.
neq.alt	integer: number of equality constraints that are maintained under the alternative hypothesis (for hypothesis test type "B"), see example 3.
boot	the null-distribution of these test-statistics (except under type "C") takes the form of a mixture of F-distributions. The tail probabilities can be computed directly via bootstrapping; if "parametric", the p-value is computed based on the parametric bootstrap. By default, samples are drawn from a normal distribution with mean zero and variance one. See p.distr for other distributional options. If "model.based", a model-based bootstrap method is used. Instead of computing the p-value via simulation, the p-value can also be computed using the chi-bar-square weights. If "no", the p-value is computed based on the weights obtained via simulation (mix_weights = "boot") or using the multivariate normal distribution function (mix_weights = "pmvnorm"). Note that, these weights are already available in the restriktor objected and do not need to be estimated again. However, there are two exception for objects of class conRLM, namely for computing the p-value for the robust test = "Wald" and the robust "score". In these cases the weights need to be recalculated.
R	integer; number of bootstrap draws for boot. The default value is set to 9999.
p.distr	random generation distribution for the parametric bootstrap. For all available distributions see ?distributions. For example, if rnorm, samples are drawn from the normal distribution (default) with mean zero and variance one. If rt, samples are drawn from a t-distribution. If rchisq, samples are drawn from a chi-square distribution. The distributional parameters will be passed in via ...
parallel	the type of parallel operation to be used (if any). If missing, the default is set "no".
ncpus	integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
cl	an optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the conTest call.
seed	seed value. The default value is set to 1234.
verbose	logical; if TRUE, information is shown at each bootstrap draw.
control	a list of control arguments: <ul style="list-style-type: none"> absval tolerance criterion for convergence (default = sqrt(.Machine\$double.eps)). Only used for model of class lm.

- `maxit` the maximum number of iterations for the optimizer (default = 10000). Only used for model of class `mlm` (not yet supported).
- `tol` numerical tolerance value. Estimates smaller than `tol` are set to 0.
- `chunk_size` the chi-bar-square weights are computed for samples of size `chunk_size = 5000L`. This process is repeated iteratively until the weights converges (see `convergence_crit`) or the maximum is reached, i.e., `mix_weights_bootstrap_limit`.
- `convergence_crit` the convergence criterion for the iterative process. The default is `1e-03`.

... Additional arguments that can be passed to the `p.distr` function, or arguments for the `restrktor` or `iht` function. Consider, for example, the `mix_weights_bootstrap_limit` control argument, which specifies the maximum number of bootstrap draws (default is 100.000) used to compute the chi-bar-square weights. If `mix_weights_bootstrap_limit` is set to 100.000, then in each iteration, a sample of size 5000 is added until the weights converge, or the maximum limit is reached.

Details

The following hypothesis tests are available:

- Type A: Test H_0 : all constraints with equalities (" $=$ ") active against H_A : at least one inequality restriction (" $>$ ") strictly true.
- Type B: Test H_0 : all constraints with inequalities (" $>$ ") (including some equalities (" $=$ ") active against H_A : at least one restriction false (some equality constraints may be maintained).
- Type C: Test H_0 : at least one restriction false (" $<$ ") against H_A : all constraints strictly true (" $>$ "). This test is based on the intersection-union principle (Silvapulle and Sen, 2005, chp 5.3). Note that, this test only makes sense in case of no equality constraints.
- Type global: equal to Type A but H_0 contains additional equality constraints. This test is analogue to the global F-test in `lm`, where all coefficients but the intercept equal 0.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequality constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

The exact finite sample distributions of the non-robust F-, score- and LR-test statistics based on restricted OLS estimates and normally distributed errors, are a mixture of F-distributions under the null hypothesis (Wolak, 1987). In agreement with Silvapulle (1992), we found that the results based on these mixtures of F-distributions approximate the tail probabilities of the robust tests better than their asymptotic distributions. Therefore, all p-values for hypothesis test Type "A", "B" and "global" are computed based on mixtures of F-distributions.

Note that, in case of equality constraints only, the null-distribution of the (robust) F-test statistics is based on an F-distribution. The (robust) Wald- and (robust) score-test statistics are based on chi-square distributions.

Value

An object of class `conTest`, for which a `print` is available. More specifically, it is a list with the following items:

`CON` a list with useful information about the constraints.

Amat	constraints matrix.
bvec	vector of right-hand side elements.
meq	number of equality constraints.
meq.alt	same as input meq.alt.
iact	number of active constraints.
type	same as input.
test	same as input.
Ts	test-statistic value.
df.residual	the residual degrees of freedom.
pvalue	tail probability for Ts.
b.eqrestr	equality restricted regression coefficients. Only available for type = "A" and type = "global", else b.eqrestr = NULL.
b.unrestr	unrestricted regression coefficients.
b.restr	restricted regression coefficients.
b.restr.alt	restricted regression coefficients under HA if some equality constraints are maintained. Only available for type = "B" else b.restr.alt = NULL.
Sigma	variance-covariance matrix of unrestricted model.
R2.org	unrestricted R-squared, not available for objects of class conGLM.
R2.reduced	restricted R-squared, not available for objects of class conGLM.
boot	same as input.
model.org	original model.

           verbose = FALSE, control = NULL, ...)

## S3 method for class 'conMLM'
conTestLRT(object, type = "A", neq.alt = 0,
           boot = "no", R = 9999, p.distr = rnorm,
           parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
           verbose = FALSE, control = NULL, ...)

```

Arguments

object	an object of class conLM, conMLM or conGLM.
type	hypothesis test type "A", "B", "C", "global", or "summary" (default). See details for more information.
neq.alt	integer: number of equality constraints that are maintained under the alternative hypothesis (for hypothesis test type "B"), see example 3.
boot	the null-distribution of these test-statistics (except under type "C", see details) takes the form of a mixture of F-distributions. The tail probabilities can be computed directly via bootstrapping; if "parametric", the p-value is computed based on the parametric bootstrap. By default, samples are drawn from a normal distribution with mean zero and variance one. See p.distr for other distributional options. If "model.based", a model-based bootstrap method is used. Instead of computing the p-value via simulation, the p-value can also be computed using the chi-bar-square weights. If "no", the p-value is computed based on the weights obtained via simulation (mix_weights = "boot") or using the multivariate normal distribution function (mix_weights = "pmvnorm"). Note that, these weights are already available in the restriktor object and do not need to be estimated again. However, there are two exceptions for objects of class conRLM, namely for computing the p-value for the robust test = "Wald" and the robust "score". In these cases the weights need to be recalculated.
R	integer; number of bootstrap draws for boot. The default value is set to 9999.
p.distr	random generation distribution for the parametric bootstrap. For all available distributions see ?distributions. For example, if rnorm, samples are drawn from the normal distribution (default) with mean zero and variance one. If rt, samples are drawn from a t-distribution. If rchisq, samples are drawn from a chi-square distribution. The random generation distributional parameters will be passed in via ...
parallel	the type of parallel operation to be used (if any). If missing, the default is set "no".
ncpus	integer: number of processes to be used in parallel operation: typically one would choose this to the number of available CPUs.
cl	an optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the conTest call.
seed	seed value. The default value is set to 1234.
verbose	logical; if TRUE, information is shown at each bootstrap draw.
control	a list of control arguments: <ul style="list-style-type: none"> • absval tolerance criterion for convergence (default = sqrt(.Machine\$double.eps)). Only used for model of class lm. • maxit the maximum number of iterations for the optimizer (default = 10000). Only used for model of class mlm (not yet supported). • tol numerical tolerance value. Estimates smaller than tol are set to 0. • chunk_size the chi-bar-square weights are computed for samples of size chunk_size = 5000L. This process is repeated iteratively until the weights converges (see convergence_crit) or the maximum is reached, i.e., mix_weights_bootstrap_limit.

- `convergence_crit` the convergence criterion for the iterative process. The default is $1e-03$.
- ...
- Additional arguments that can be passed to the `p.distr` function, or arguments for the `restriktor` or `iht` function. Consider, for example, the `mix_weights_bootstrap_limit` argument, which specifies the maximum number of bootstrap draws (default is 100.000) used to compute the chi-bar-square weights. If `mix_weights_bootstrap_limit` is set to 100.000, then in each iteration, a sample of size 5000 is added until the weights converge, or the maximum limit is reached.

Details

The following hypothesis tests are available:

- Type A: Test H0: all constraints with equalities ("=") active against HA: at least one inequality restriction (">") strictly true.
- Type B: Test H0: all constraints with inequalities(">") (including some equalities ("=")) active against HA: at least one restriction false (some equality constraints may be maintained).
- Type C: Test H0: at least one restriction false ("<") against HA: all constraints strictly true (">"). This test is based on the intersection-union principle (Silvapulle and Sen, 2005, chp 5.3). Note that, this test only makes sense in case of no equality constraints.
- Type global: equal to Type A but H0 contains additional equality constraints. This test is analogue to the global F-test in `lm`, where all coefficients but the intercept equal 0.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequality constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

The exact finite sample distributions of the non-robust F-, score- and LR-test statistics based on restricted OLS estimates and normally distributed errors, are a mixture of F-distributions under the null hypothesis (Wolak, 1987). In agreement with Silvapulle (1992), we found that the results based on these mixtures of F-distributions approximate the tail probabilities of the robust tests better than their asymptotic distributions. Therefore, all p-values for hypothesis test Type "A", "B" and "global" are computed based on mixtures of F-distributions.

Value

An object of class `conTest`, for which a `print` is available. More specifically, it is a list with the following items:

<code>CON</code>	a list with useful information about the constraints.
<code>Amat</code>	constraints matrix.
<code>bvec</code>	vector of right-hand side elements.
<code>meq</code>	number of equality constraints.
<code>meq_alt</code>	same as input <code>meq.alt</code> .
<code>iact</code>	number of active constraints.
<code>type</code>	same as input.
<code>test</code>	same as input.

Ts	test-statistic value.
df.residual	the residual degrees of freedom.
pvalue	tail probability for Ts.
b_eqrestr	equality restricted regression coefficients. Only available for type = "A" and type = "global", else b.eqrestr = NULL.
b_unrestr	unrestricted regression coefficients.
b_restr	restricted regression coefficients.
b_restr_alt	restricted regression coefficients under HA if some equality constraints are maintained. Only available for type = "B" else b_restr_alt = NULL.
Sigma	variance-covariance matrix of unrestricted model.
R2_org	unrestricted R-squared, not available for objects of class conGLM.
R2_reduced	restricted R-squared, not available for objects of class conGLM.
boot	same as input.
model_org	original model.

conTestScore	<i>Score-bar test for iht</i>
--------------	-------------------------------

Description

conTestScore tests linear equality and/or inequality restricted hypotheses for (robust) linear models by score-tests. It can be used directly and is called by the conTest function if test = "score".

Usage

```
## S3 method for class 'conLM'
conTestScore(object, type = "A", neq.alt = 0,
             boot = "no", R = 9999, p.distr = rnorm,
             parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
             verbose = FALSE, control = NULL, ...)

## S3 method for class 'conRLM'
conTestScore(object, type = "A", neq.alt = 0,
             boot = "no", R = 9999, p.distr = rnorm,
             parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
             verbose = FALSE, control = NULL, ...)

## S3 method for class 'conGLM'
conTestScore(object, type = "A", neq.alt = 0,
             boot = "no", R = 9999, p.distr = rnorm,
             parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
             verbose = FALSE, control = NULL, ...)
```

Arguments

object	an object of class conLM, conRLM or conGLM.
type	hypothesis test type "A", "B", "C", "global", or "summary" (default). See details for more information.
neq.alt	integer: number of equality constraints that are maintained under the alternative hypothesis (for hypothesis test type "B"), see example 3.
boot	the null-distribution of these test-statistics (except under type "C", see details) takes the form of a mixture of F-distributions. The tail probabilities can be computed directly via bootstrapping; if "parametric", the p-value is computed based on the parametric bootstrap. By default, samples are drawn from a normal distribution with mean zero and variance one. See p.distr for other distributional options. If "model.based", a model-based bootstrap method is used. Instead of computing the p-value via simulation, the p-value can also be computed using the chi-bar-square weights. If "no", the p-value is computed based on the weights obtained via simulation (mix_weights = "boot") or using the multivariate normal distribution function (mix_weights = "pmvnorm"). Note that,

these weights are already available in the restriktor objected and do not need to be estimated again. However, there are two exception for objects of class conRLM, namely for computing the p-value for the robust test = "Wald" and the robust "score". In these cases the weights need to be recalculated.

R	integer; number of bootstrap draws for boot. The default value is set to 9999.
p.distr	random generation distribution for the parametric bootstrap. For all available distributions see ?distributions. For example, if rnorm, samples are drawn from the normal distribution (default) with mean zero and variance one. If rt, samples are drawn from a t-distribution. If rchisq, samples are drawn from a chi-square distribution. The random generation distributional parameters will be passed in via
parallel	the type of parallel operation to be used (if any). If missing, the default is set "no".
ncpus	integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
cl	an optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the conTest call.
seed	seed value. The default value is set to 1234.
verbose	logical; if TRUE, information is shown at each bootstrap draw.
control	a list of control arguments: <ul style="list-style-type: none"> • absval tolerance criterion for convergence (default = sqrt(.Machine\$double.eps)). Only used for model of class lm. • maxit the maximum number of iterations for the optimizer (default = 10000). Only used for model of class mlm (not yet supported). • tol numerical tolerance value. Estimates smaller than tol are set to 0. • chunk_size the chi-bar-square weights are computed for samples of size chunk_size = 5000L. This process is repeated iteratively until the weights converges (see convergence_crit) or the maximum is reached, i.e., mix_weights_bootstrap_limit. • convergence_crit the convergence criterion for the iterative process. The default is 1e-03.
. . .	Additional arguments that can be passed to the p.distr function, or arguments for the restriktor or iht function. Consider, for example, the mix_weights_bootstrap_limit argument, which specifies the maximum number of bootstrap draws (default is 100.000) used to compute the chi-bar-square weights. If mix_weights_bootstrap_limit is set to 100.000, then in each iteration, a sample of size 5000 is added until the weights converge, or the maximum limit is reached.

Details

The following hypothesis tests are available:

- Type A: Test H0: all constraints with equalities ("=") active against HA: at least one inequality restriction (">") strictly true.
- Type B: Test H0: all constraints with inequalities (">") (including some equalities ("=")) active against HA: at least one restriction false (some equality constraints may be maintained).

- Type C: Test H0: at least one restriction false (" $<$ ") against HA: all constraints strictly true (" $>$ "). This test is based on the intersection-union principle (Silvapulle and Sen, 2005, chp 5.3). Note that, this test only makes sense in case of no equality constraints.
- Type global: equal to Type A but H0 contains additional equality constraints. This test is analogue to the global F-test in lm, where all coefficients but the intercept equal 0.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequality constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

The exact finite sample distributions of the non-robust F-, score- and LR-test statistics based on restricted OLS estimates and normally distributed errors, are a mixture of F-distributions under the null hypothesis (Wolak, 1987). In agreement with Silvapulle (1992), we found that the results based on these mixtures of F-distributions approximate the tail probabilities of the robust tests better than their asymptotic distributions. Therefore, all p-values for hypothesis test Type "A", "B" and "global" are computed based on mixtures of F-distributions.

Value

An object of class `conTest`, for which a `print` is available. More specifically, it is a list with the following items:

<code>CON</code>	a list with useful information about the constraints.
<code>Amat</code>	constraints matrix.
<code>bvec</code>	vector of right-hand side elements.
<code>meq</code>	number of equality constraints.
<code>meq.alt</code>	same as input <code>neq.alt</code> .
<code>iact</code>	number of active constraints.
<code>type</code>	same as input.
<code>test</code>	same as input.
<code>Ts</code>	test-statistic value.
<code>df.residual</code>	the residual degrees of freedom.
<code>pvalue</code>	tail probability for <code>Ts</code> .
<code>b.eqrestr</code>	equality restricted regression coefficients. Only available for <code>type = "A"</code> and <code>type = "global"</code> , else <code>b.eqrestr = NULL</code> .
<code>b.unrestr</code>	unrestricted regression coefficients.
<code>b.restr</code>	restricted regression coefficients.
<code>b.restr.alt</code>	restricted regression coefficients under HA if some equality constraints are maintained. Only available for <code>type = "B"</code> else <code>b.restr.alt = NULL</code> .
<code>Sigma</code>	variance-covariance matrix of unrestricted model.
<code>R2.org</code>	unrestricted R-squared, not available for objects of class <code>conGLM</code> .
<code>R2.reduced</code>	restricted R-squared, not available for objects of class <code>conGLM</code> .
<code>boot</code>	same as input.
<code>model.org</code>	original model.

conTestWald

Wald-bar test for robust iht

Description

conTestWald tests linear equality and/or inequality restricted hypotheses for linear models by Wald-tests. It can be used directly and is called by the conTest function if test = "Wald".

Usage

```

## S3 method for class 'conRLM'
conTestWald(object, type = "A", neq.alt = 0,
            boot = "no", R = 9999, p.distr = rnorm,

```

```
parallel = "no", ncpus = 1L, cl = NULL, seed = 1234,
verbose = FALSE, control = NULL, ...)
```

Arguments

object	an object of class conRLM.
type	hypothesis test type "A", "B", "C", "global", or "summary" (default). See details for more information.
neq.alt	integer: number of equality constraints that are maintained under the alternative hypothesis (for hypothesis test type "B"), see example 3.
boot	the null-distribution of these test-statistics (except under type "C", see details) takes the form of a mixture of F-distributions. The tail probabilities can be computed directly via bootstrapping; if "parametric", the p-value is computed based on the parametric bootstrap. By default, samples are drawn from a normal distribution with mean zero and variance one. See p.distr for other distributional options. If "model.based", a model-based bootstrap method is used. Instead of computing the p-value via simulation, the p-value can also be computed using the chi-bar-square weights. If "no", the p-value is computed based on the weights obtained via simulation (mix_weights = "boot") or using the multivariate normal distribution function (mix_weights = "pmvnorm"). Note that, these weights are already available in the restriktor object and do not need to be estimated again. However, there are two exceptions for objects of class conRLM, namely for computing the p-value for the robust test = "Wald" and the robust "score". In these cases the weights need to be recalculated.
R	integer; number of bootstrap draws for boot. The default value is set to 9999.
p.distr	random generation distribution for the parametric bootstrap. For all available distributions see ?distributions. For example, if rnorm, samples are drawn from the normal distribution (default) with mean zero and variance one. If rt, samples are drawn from a t-distribution. If rchisq, samples are drawn from a chi-square distribution. The random generation distributional parameters will be passed in via
parallel	the type of parallel operation to be used (if any). If missing, the default is set "no".
ncpus	integer: number of processes to be used in parallel operation: typically one would choose this to the number of available CPUs.
cl	an optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the conTest call.
seed	seed value. The default value is set to 1234.
verbose	logical; if TRUE, information is shown at each bootstrap draw.
control	a list of control arguments: <ul style="list-style-type: none"> • absval tolerance criterion for convergence (default = sqrt(.Machine\$double.eps)). Only used for model of class lm. • maxit the maximum number of iterations for the optimizer (default = 10000). Only used for model of class mlm (not yet supported). • tol numerical tolerance value. Estimates smaller than tol are set to 0.

- `chunk_size` the chi-bar-square weights are computed for samples of size `chunk_size = 5000`. This process is repeated iteratively until the weights converges (see `convergence_crit`) or the maximum is reached, i.e., `mix_weights_bootstrap_limit`.
- `convergence_crit` the convergence criterion for the iterative process. The default is `1e-03`.

... Additional arguments that can be passed to the `p.distr` function, or arguments for the `restrktor` or `iht` function. Consider, for example, the `mix_weights_bootstrap_limit` argument, which specifies the maximum number of bootstrap draws (default is 100.000) used to compute the chi-bar-square weights. If `mix_weights_bootstrap_limit` is set to 100.000, then in each iteration, a sample of size 5000 is added until the weights converge, or the maximum limit is reached.

Details

The following hypothesis tests are available:

- Type A: Test H0: all constraints with equalities ("`=`") active against HA: at least one inequality restriction ("`>`") strictly true.
- Type B: Test H0: all constraints with inequalities ("`>`") (including some equalities ("`=`") active against HA: at least one restriction false (some equality constraints may be maintained).
- Type C: Test H0: at least one restriction false ("`<`") against HA: all constraints strictly true ("`>`"). This test is based on the intersection-union principle (Silvapulle and Sen, 2005, chp 5.3). Note that, this test only makes sense in case of no equality constraints.
- Type global: equal to Type A but H0 contains additional equality constraints. This test is analogue to the global F-test in `lm`, where all coefficients but the intercept equal 0.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequality constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

The exact finite sample distributions of the non-robust F-, score- and LR-test statistics based on restricted OLS estimates and normally distributed errors, are a mixture of F-distributions under the null hypothesis (Wolak, 1987). In agreement with Silvapulle (1992), we found that the results based on these mixtures of F-distributions approximate the tail probabilities of the robust tests better than their asymptotic distributions. Therefore, all p-values for hypothesis test Type "A", "B" and "global" are computed based on mixtures of F-distributions.

Value

## S3 method for class 'conRLM'
conTest_ceq(object, test = "F", boot = "no",
            R = 9999, p.distr = rnorm, parallel = "no",
            ncpus = 1L, cl = NULL, seed = 1234, verbose = FALSE, ...)

## S3 method for class 'conGLM'
conTest_ceq(object, test = "F", boot = "no",
            R = 9999, p.distr = rnorm, parallel = "no",
            ncpus = 1L, cl = NULL, seed = 1234, verbose = FALSE, ...)

```

Arguments

object	an object of class conLM, conRLM or conGLM.
test	test statistic; for information about the null-distribution see details. <ul style="list-style-type: none"> • for object of class lm and glm; if "F" (default), the classical F-statistic is computed. If "Wald", the classical Wald-statistic is computed. If "score", the classical score test statistic is computed. • for object of class rlm; if "F" (default), a robust likelihood ratio type test statistic (Silvapulle, 1992a) is computed. If "Wald", a robust Wald test statistic (Silvapulle, 1992b) is computed. If "score", a score test statistic (Silvapulle, 1996) is computed.

boot	if "parametric", the p-value is computed based on the parametric bootstrap. See p.distr for available distributions. If "model.based", a model-based bootstrap method is used. Model-based bootstrapping is not supported for the conGLM object yet.
R	integer; number of bootstrap draws for boot. The default value is set to 9999.
p.distr	the p.distr function is specified by this function. For all available distributions see ?distributions. For example, if rnorm, samples are drawn from the normal distribution (default) with mean zero and variance one. If rt, samples are drawn from a t-distribution. If rchisq, samples are drawn from a chi-square distribution. The distributional parameters will be passed in via ...
parallel	the type of parallel operation to be used (if any). If missing, the default is set "no".
ncpus	integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
cl	an optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the conTest call.
seed	seed value. The default value is set to 1234.
verbose	logical; if TRUE, information is shown at each bootstrap draw.
...	additional arguments to be passed to the p.distr function.

Value

An object of class `conTest`, for which a `print` is available. More specifically, it is a list with the following items:

CON	a list with useful information about the constraints.
Amat	constraints matrix.
bvec	vector of right-hand side elements.
meq	number of equality constraints.
test	same as input.
Ts	test-statistic value.
df.residual	the residual degrees of freedom.
pvalue	tail probability for Ts.
b_unrestr	unrestricted regression coefficients.
b_restr	restricted regression coefficients.
R2_org	unrestricted R-squared.
R2_reduced	restricted R-squared.

conTest_summary *function for computing all available hypothesis tests*

Description

conTest_summary computes all available hypothesis tests and returns an object of class conTest for which a print function is available. The conTest_summary can be used directly and is called by the conTest function if type = "summary".

Usage

```
## S3 method for class 'restriktor'
conTest_summary(object, test = "F", ...)
```

Arguments

object	an object of class restriktor.
test	test statistic; for information about the null-distribution see details. <ul style="list-style-type: none"> • for object of class lm; if "F" (default), the classical F-statistic is computed. If "Wald", the classical Wald-statistic is computed. If "score", the classical score test statistic is computed. • for object of class rlm; if "F" (default), a robust likelihood ratio type test statistic (Silvapulle, 1992a) is computed. If "Wald", a robust Wald test statistic (Silvapulle, 1992b) is computed. If "score", a score test statistic (Silvapulle, 1996) is computed.
...	the same arguments as passed to the iht function, except for type, of course.

Value

An object of class conTest, for which a print is available. More specifically, it is a list with the following items:

CON	a list with useful information about the constraints.
Amat	constraints matrix.
bvec	vector of right-hand side elements.
meq	number of equality constraints.
meq.alt	same as input neq.alt.
iact	number of active constraints.
type	same as input.
test	same as input.

Ts	test-statistic value.
df.residual	the residual degrees of freedom.
pvalue	tail probability for Ts.
b.eqrestr	equality restricted regression coefficients. Only available for type = "A" and type = "global", else b.eqrestr = NULL.
b.unrestr	unrestricted regression coefficients.
b.restr	restricted regression coefficients.
b.restr.alt	restricted regression coefficients under HA if some equality constraints are maintained.
Sigma	variance-covariance matrix of unrestricted model.
R2.org	unrestricted R-squared.
R2.reduced	restricted R-squared.
boot	same as input.
model.org	original model.

con_weights_boot

function for computing the chi-bar-square weights based on Monte Carlo simulation.

Description

The null-distribution of the test statistics under inequality constraints takes the form of mixtures of F-distributions. This function computes these mixing weights (a.k.a chi-bar-square weights and level probabilities).

Usage

```
con_weights_boot(VCOV, Amat, meq, R = 1e5L,
                 chunk_size = 5000L, convergence_crit = 1e-03,
                 seed = NULL, verbose = FALSE, ...)
```

Arguments

VCOV	variance-covariance matrix of the data for which the weights are to be calculated.
Amat	constraints matrix R (or a vector in case of one constraint) and defines the left-hand side of the constraint $R\theta \geq rhs$, where each row represents one constraint. The number of columns needs to correspond to the number of parameters estimated (θ). The rows should be linear independent, otherwise the function gives an error. For more information about constructing the matrix R and rhs see restriktor .
meq	integer (default = 0) treating the number of constraints rows as equality constraints instead of inequality constraints. For example, if <code>meq = 2</code> , this means that the first two rows of the constraints matrix R are treated as equality constraints.
R	integer; the maximum number of bootstrap draws for <code>mix_weights_bootstrap_limit</code> . The default value is set to <code>1e5</code> . See details for more information.
chunk_size	integer; the chi-bar-square weights are computed for samples of size <code>chunk_size = 5000L</code> . This process is repeated iteratively until the weights converges (see <code>convergence_crit</code>) or the maximum is reached, i.e., <code>mix_weights_bootstrap_limit</code> .
convergence_crit	the convergence criterion for the iterative process. The default is <code>1e-03</code> . See details for more information.
seed	seed value.
verbose	logical; if TRUE, information is shown at each bootstrap draw.
...	additional parameters for the <code>rtmvnorm</code> function.

Details

Iterative Weight Updating and Convergence Checking ## The function adds in each run chunks of 5000 samples (default) to compute the chi-bar-square weights. After each iteration, the function checks if the weights have converged. This is determined by the `convergence_crit` parameter.

Convergence is assessed by comparing the absolute difference between the current and previous iteration's weights against the `convergence_crit`. If the change in weights is smaller than the convergence criterion, it indicates that the weights have stabilized, suggesting convergence.

If the weights have not converged and the `mix_weights_bootstrap_limit` has not been reached, the function proceeds with adding another set of 5000 samples and updates the weights accordingly. If the maximum number of iterations is reached without convergence, the function returns the (non-converged) weights. In this situation, it is advisable to increase the number of `mix_weights_bootstrap_limit`.

Value

If convergence is reached, the function returns a vector with the mixing weights with the following attributes:

total_bootstrap_draws	total number of bootstrap draws
converged	have the chi-bar-square weights converged
convergence_crit	convergence criterium
wt_bar_chunk	matrix with the chi-bar-square weights for each iteration
chunk_size	how many samples are added in each iteration
total_chunks	what is the maximum number of chunks based on mix_weights_bootstrap_limit and chunk_size
chunk_iter	number of iterations run
error.idx	which bootstrap samples were not succesful
mix_weights_bootstrap_limit	the maximum number of bootstrap draws

Examples

```
W <- matrix(c(1,0.5,0.5,1),2,2)
Amat <- rbind(c(0,1))
meq <- 0L
wt.bar <- con_weights_boot(W, Amat, meq, R = 99999)
wt.bar

# in practice you want to use are more conservative convergence criterion
wt.bar2 <- con_weights_boot(W, Amat, meq, R = 99999, convergence_crit = 1e-02)
wt.bar2
```

 evSyn

GORIC(A) Evidence synthesis

Description

GORIC(A) evidence synthesis aggregates the evidence for theory-based hypotheses from multiple studies that may use diverse designs to investigate the same central theory.

Usage

```
# I try to guess the input type.
evSyn(object, input_type = NULL, ...)

# input: Parameter estimates and covariance matrix
evSyn_est(object, ..., VCOV = list(), hypotheses = list(),
           type = c("added", "equal", "average"),
           comparison = c("unconstrained", "complement", "none"),
           hypo_names = c())

# input: Log-likelihood and penalty values
evSyn_LL(object, ..., PT = list(), type = c("added", "equal", "average"),
          hypo_names = c())

# input: GORIC(A), ORIC, AIC values
evSyn_ICvalues(object, ..., hypo_names = c())

# input: AIC or ORIC or GORIC or GORICA weights or (Bayesian) posterior
# model probabilities
evSyn_ICweights(object, ..., priorWeights = NULL, hypo_names = c())

# input: Ratio of AIC or ORIC or GORIC or GORICA weights or
# (Bayesian) posterior model probabilities
evSyn_ICratios(object, ..., priorWeights = NULL, hypo_names = c())

# input: result from the goric() function
# Note that this is a wrapper function for evSyn_LL.
evSyn_gorica(object, ..., type = c("added", "equal", "average"), hypo_names = c())

# input: Result from the escalc() function from the metafor package.
# Note that this is a wrapper function for evSyn_est.
evSyn_escalc(data, yi_col = "yi", vi_cols = "vi", cluster_col, outcome_col, ...)

## S3 method for class 'evSyn'
print(x, digits = max(3, getOption("digits") - 4), ...)

## S3 method for class 'evSyn'
summary(object, ...)
```

```
## S3 method for class 'summary.evSyn'
print(x, digits = max(3, getOption("digits") - 4), ...)

## S3 method for class 'evSyn'
plot(x, output_type = "gorica_weights", xlab = NULL, ...)
```

Arguments

object	<p>Currently, the following objects can be processed:</p> <ul style="list-style-type: none"> • a list of vectors with (standardized) parameter estimates (the VCOV argument is required); • a list of vectors with log-likelihood values (the PT argument is required); • a list of vectors with GORIC(A) weights; • a list of vectors with ratio of GORIC(A) weights; • a list of vectors with GORIC(A) values; • a list of objects of class goric; • a data.frame of class escalc from the metafore package;
input_type	<p>character Specifies the type of input provided to the function. Valid options are:</p> <p>"est_vcov" Indicates that the input consists of estimates and covariance matrices. Invokes the evSyn_est() function.</p> <p>"ll_pt" Indicates that the input consists of log-likelihoods and penalty values. Invokes the evSyn_LL() function.</p> <p>"icweights" Indicates that the input consists of information criterion (IC) weights. Invokes the evSyn_ICweights() function.</p> <p>"icratios" Indicates that the input consists of IC weights ratios. Invokes the evSyn_ICratios() function.</p> <p>"icvalues" Indicates that the input consists of IC values. Invokes the evSyn_ICvalues() function.</p> <p>"gorica" Indicates that the input is of class goric from the goric function. Invokes the evSyn_gorica() function.</p> <p>"escalc" Indicates that the input is of class escalc from the metafor package. Invokes the evSyn_escalc() function.</p> <p>If input_type is NULL, the function attempts to infer the input type based on the structure of the object and other arguments.</p>
VCOV	a list of covariance matrices of the (standardized) parameter estimates of interest.
PT	a list of vectors with penalty values.
x	an object of class evSyn
type	type of evidence-synthesis approach: Equal-evidence approach (type = "equal"), Added-evidence approach (type = "added"), or Average-evidence approach (type = "average"). See details for more information.
hypotheses	When applying the same set of hypotheses to each study, the syntax structure should be as follows: "hypotheses = list(H1, H2, ...)". However, if a different

set of hypotheses is applied to each study, the syntax structure should be as follows: `hypotheses = list(set1 = list(H11, H12), set2 = list(H21, H22))`. See [goric](#) how to specify the hypotheses syntax or see the example section below.

comparison	if "unconstrained" (default) the unconstrained model is included in the set of models. If "complement" then the restricted object is compared against its complement. Note that the complement can only be computed for one model/hypothesis at a time (for now). If "none" the model is only compared against the models provided by the user.
priorWeights	vector that represents the prior belief for this model. By default, equal prior weights are used (i.e., $1/(\#hypotheses)$). Notably, in case the prior weights do not sum to 1, it will be rescaled such that it does; which implies that relative importance can be used and not per se weights.
hypo_names	character vector for labelling the hypotheses. By default the names are set to H1, H2, ...
output_type	if "gorica_weights", a plot with the cumulative <code>goric(a)</code> weights and <code>goric(a)</code> weights per study is displayed. If "ll_weights" a plot with the cumulative log-likelihood weights and log-likelihood weights per study is displayed.
xlab	a vector specifying custom labels for the x-axis. The length of the vector must match the number of studies in the dataset. If not provided, the x-axis labels default to a sequence from 1 to the number of studies.
data	an object of class "escal" from the metafor package.
outcome_col	an optional column name in data containing the outcome identifiers for each observation within a cluster. If NULL, the function assumes the outcome identifier is "yi" (one outcome variable).
yi_col	a character string specifying the column in data that contains the outcome values for each observation. The default is "yi" (one outcome variable).
vi_cols	a character vector specifying the columns in data that contain the variance and covariance values for each observation. The default is "vi" (one outcome variable).
cluster_col	a character string specifying the column in data that contains the cluster identifier. Observations within the same cluster should share the same value in this column. The default is "trial", other usual suspects are "study" and "author".
digits	the number of significant digits to use when printing.
...	This depends on the class of the object.

Details

In the **added-evidence** approach, evidence from each study or dataset is cumulatively aggregated. This means that for every new study, the log-likelihood and the penalty term are added to the cumulative totals. The strength of the aggregated evidence in this approach depends on the nature of the evidence itself. Simply having more studies doesn't necessarily mean stronger evidence if those studies provide weak or contradictory evidence.

Opt for this approach when you anticipate each new piece of evidence to provide an incremental contribution to the overall evidence, without the need to normalize or average across datasets. It's

especially suitable when you believe that the aggregated evidence from multiple studies is stronger than if the data were combined into a single study.

The **equal-evidence** approach aggregates the cumulative evidence in the same manner as the added-evidence approach. However, when calculating the GORICA, the cumulative evidence is divided by the number of studies. This ensures that the contribution from each study or dataset remains equal, regardless of the total count. Conceptually, aggregating evidence from multiple studies in this approach can be likened to obtaining evidence from a single larger study, similar to how a meta-analysis treats combined evidence.

Choose this method when you want each study to contribute equally to the overall evidence, irrespective of the size or scope of each individual dataset. It's ideal for situations where you view the combined evidence from multiple studies as equivalent to that from a single, larger study.

The **average-evidence** method can be conceptualized as a form of multiverse analysis. When faced with a single dataset, there are often numerous analytical choices available, such as handling missing data, selecting variables, or choosing statistical methods. Each choice can lead to a different analysis or model, creating a "multiverse" of possible outcomes.

For each of these analyses, an "evidence" score can be calculated, indicating how well the model fits the data. Some models might offer a superior fit, while others might not align as closely with the data. The average-evidence method aggregates these scores, providing an average measure of fit across all considered models. This approach offers an overarching perspective on the general trend across all analyses. If the average evidence suggests a good fit, it indicates that the majority of the chosen analyses align well with the data. This method is invaluable for assessing the robustness of results, ensuring that findings are not merely artifacts of a specific analytical choice but are consistent across various model specifications on the same dataset.

Opt for the average-evidence approach when you wish to gauge the central tendency of evidence across multiple analytical choices. It's especially beneficial when aiming to determine the robustness of results across various model specifications applied to the same dataset.

Value

An object of class `evSyn` for which a `print`, `summary` and `plot` function is available. The output comprises, among other things, the cumulative and final evidence for the theory-based hypotheses.

Author(s)

Leonard Vanbrabant and Rebecca Kuiper

Examples

```
## By following these examples, you can appropriately specify hypotheses based on
## your research questions and analytical framework.

# The hypotheses (i.e., constraints) have to be in a list. It is recommended to name
# each hypothesis in the list. Otherwise the hypotheses are named accordingly 'H1', 'H2', \dots

# text-based syntax (the labels x1, x2, and x3 are the names of coef(model) or names(vector))
h1 <- '(x1, x2, x3) > 0'
h2 <- '(x1, x3) > 0; x2 = 0'
h3 <- 'x1 > 0; x2 < 0; x3 = 0'
hypotheses = list(hypo1 = h1, hypo2 = h2, hypo3 = h3)
```

```

# mixed syntax:
hypotheses = list(Ha = h1, Hb = 'x1 = x2 > x3')

# the same set of hypotheses for each study:
# hypotheses = list(H1, H2, \ldots)

# a different set of hypotheses for each study:
# note that the list names set1 and set2 are redundant and can be left out.
# It is crucial to ensure that the hypotheses across each set are ordered in a similar manner.

H11 <- 'group1 = group2 > group3'
H12 <- 'group2 > group1 > group3'

H21 <- 'gr1 = gr2 > gr3'
H22 <- 'gr2 > gr1 > gr3'

# correct
hypotheses = list(set1 = list(H11, H12), set2 = list(H21, H22))

# NOT correct
hypotheses = list(set1 = list(H12, H11), set2 = list(H21, H22))

## Example 1 - 4 studies
est_1 <- c(beta1 = 0.09)
est_2 <- c(beta1 = 0.14)

```

Exam

Relation between exam scores and study hours, anxiety scores and average point scores.

Description

The data provide information about students' exam scores, average point score, the amount of study hours and anxiety scores.

Usage

```
data(Exam)
```

Format

A data frame of 20 observations of 4 variables.

Scores exam scores

Hours study hours

Anxiety anxiety scores

APS average point score

References

The original source of these data is <http://staff.bath.ac.uk/pssiw/stats2/examrevision.sav>.

Examples

```
head(Exam)
```

FacialBurns

Dataset for illustrating the conTest_conLavaan function.

Description

A dataset from the Dutch burn center (<http://www.adbc.nl>). The data were used to examine psychosocial functioning in patients with facial burn wounds. Psychosocial functioning was measured by Anxiety and depression symptoms (HADS), and self-esteem (Rosenberg's self-esteem scale).

Usage

```
data(FacialBurns)
```

Format

A data frame of 77 observations of 6 variables.

Selfesteem Rosenberg's self-esteem scale

HADS Anxiety and depression scale

Age Age measured in years, control variable

TBSA Total Burned Surface Area

RUM Rumination, control variable

Sex Gender, grouping variable

Examples

```
head(FacialBurns)

coef(object, ...)

```

Arguments

object	<p>an object containing the outcome of an unconstrained statistical analysis. Currently, the following objects can be processed:</p> <ul style="list-style-type: none"> • a fitted unconstrained object of class <code>lm</code>, <code>r1m</code> or <code>glm</code>. • a numeric vector containing the unconstrained estimates resulting from any statistical analysis. • a fitted object of class <code>lavaan</code>. See examples on how to specify the hypotheses. • a fitted object of class <code>CTmeta</code>. • a fitted object of class <code>rma</code>. • a fitted object of class <code>n1merMod</code>. • a fitted object of class <code>glmerMod</code>. • a fitted object of class <code>lmerMod</code>.
x	an object of class <code>con_goric</code> .
...	<p>this depends on the class of the object. If object is of class <code>lavaan</code>, the standardized or unstandardized <code>vcov</code> can be used, using setting <code>standardized = TRUE</code>. See details for more information.</p> <p><i>Options for calculating the chi-bar-square weights:</i></p> <p>Parameters passed to the truncated multivariate normal distribution. By default, <code>restriktor</code> (i.e. <code>con_weights_boot</code> function) uses no truncation points for calculating the chi-bar-square weights, which renders to the multivariate normal distribution. See the manual page of the <code>rtmvnorm</code> function from the rtmvnorm to see how to specify a truncated mvnorm distribution and the possible arguments.</p>
hypotheses	<p>a named list; Please note that the hypotheses argument in the given context serves the same purpose as the constraints argument utilized in the <code>restriktor</code> function. The distinction between them is solely semantic.</p> <p>There are two ways to constrain parameters. First, the hypothesis syntax consists of one or more text-based descriptions, where the syntax can be specified as a literal string enclosed by single quotes. Only the names of <code>coef(model)</code> or <code>names(vector)</code> can be used as names. See details for more information. Note that objects of class <code>"mlm"</code> do not (yet) support this method.</p> <p>Second, the hypothesis syntax consists of a matrix R (or a vector in case of one constraint) and defines the left-hand side of the constraint $R\theta \geq rhs$, where each row represents one constraint. The number of columns needs to correspond to the number of parameters estimated (θ) by model. The rows should be linear independent, otherwise the function gives an error. For more information about constructing the matrix R and rhs see details.</p>

comparison	<p>The default behavior depends on the number of user-specified order-restricted hypotheses. If a single hypothesis is specified, it is compared against its complement by default. When multiple order-restricted hypotheses are specified, the unconstrained model is added as a safeguard to the set of hypotheses.</p> <p>These default settings can be overridden. Use "unconstrained" to include the unconstrained model in the set of models. Use "complement" to compare the order-restricted object against its complement; note that the complement can only be computed for one model/hypothesis at a time for now. If "none" is chosen, the model is compared only against those provided by the user.</p>
VCOV	variance-covariance matrix. Only needed if object is of class numeric and type = "gorica" or type = "goricac".
sample_nobs	the number of observations if type = "goricac". Note that, if type = "goricc", the number of observations are inherited from the fitted object.
type	if "goric", the generalized order-restricted information criterion value is computed. If "gorica" the log-likelihood is computed using the multivariate normal distribution function.
penalty_factor	The penalty factor adjusts the penalty in the GORIC(A) formula ($\text{GORIC(A)} = -2 \times \text{log-likelihood} + \text{penalty_factor} \times \text{penalty}$). By default, GORIC(A) uses a penalty factor of 2, but penalty factor allows this to be customized. Higher values of penalty factor place a stronger emphasis on model simplicity, helping to prevent overfitting by penalizing complex models more heavily.
Heq	If TRUE, the null hypothesis is added to the set of models. This means that all inequality constraints are replaced with equality constraints, effectively testing the hypothesis that the parameters satisfy exact equality rather than inequality. Defaults to FALSE.
missing	the default setting for objects of class "lm" is listwise: all cases with missing values are removed from the data before the analysis. This is only valid if the data are missing completely at random (MCAR). Another option is to use "two.stage". In this approach, missing data are imputed using an EM algorithm. However, we cannot use the complete data as input for further analyses, because the resulting complete data variance-covariance matrix will not be correct. Therefore, we compute the correct asymptotic covariance (Savalei and Bentler, 2009) and use it as input for the <code>goric.numeric</code> function to compute a GORICA(C) value. Note that, the parameter estimates are also recomputed using the complete data.
auxiliary	Vector. The inclusion of auxiliary variables can improve the imputation model. These auxiliary variables are not part of the target model.
emControl	a list of control arguments for the <code>emnorm</code> function from the norm package.
standardized	if TRUE, standardized parameter estimates are used.
digits	the number of significant digits to use when printing.
debug	if TRUE, debugging information is printed out.
Control options for calculating the chi-bar-square weights:	
control	<ul style="list-style-type: none"> • <code>chunk_size</code> integer; the chi-bar-square weights are computed for samples of size <code>chunk_size = 5000L</code>. This process is repeated iteratively until the

weights converges (see `convergence_crit`) or the maximum is reached, i.e., `mix_weights_bootstrap_limit`.

- `mix_weights_bootstrap_limit` integer; maximum number of bootstrap draws. The default value is set to $1e5$.
- `convergence_crit` the convergence criterion for the iterative bootstrap process. Default is $1e-03$.

`brief` if TRUE, a short overview is printed.

Details

The GORIC(A) values themselves are not interpretable and the interest lie in their differences. The GORIC(A) weights reflect the support of each hypothesis in the set. To compare two hypotheses (and not one to the whole set), one can examine the ratio of the two corresponding GORIC(A) weights. To avoid selecting a weakly supported hypothesis as the best one, the unconstrained hypothesis is usually included as safeguard.

In case of one order-constrained hypothesis, say H_1 , the complement H_c can be computed as competing hypothesis. The complement is defined as $H_c = \text{not } H_1$.

The hypothesis syntax can be parsed via the `hypotheses` argument. If the object is an unconstrained model of class `lm`, `r1m` or `glm`, then the hypotheses can be specified in two ways, see `restriktor`. Note that if the hypotheses are written in matrix notation, then the hypotheses for each model/hypothesis is put in a named list with specific names `constraints`, `rhs`, and `neq`. For example with three parameters x_1 , x_2 , x_3 , and $x_1 > 0$: `list(model1 = list(constraints = rbind(c(1, 0, 0)), rhs = 0, neq = 0))`. The `rhs` and `neq` are not required if they are equal to 0. If `type = "gorica"`, then the object might be a (named) numeric vector. The hypotheses can again be specified in two ways, see `restriktor`. For examples, see below.

To determine the penalty term values, the chi-bar-square weights (a.k.a. level probabilities) must be computed. If `"mix_weights = "pmvnorm"` (default), the chi-bar-square weights are computed based on the multivariate normal distribution function with additional Monte Carlo steps. If `"mix_weights = "boot"`, the chi-bar-square weights are computed using parametric bootstrapping (see `restriktor`).

The "two.stage" approach for missing data uses the EM algorithm from the `norm` package. The response variables are assumed to be jointly normal. In practice, missing-data procedures designed for variables that are normal are sometimes applied to variables that are not. Binary and ordinal variables are sometimes imputed under a normal model, and the imputed values may be classified or rounded. This is also how `restriktor` handles (ordered) factors for now.

A better strategy (not implemented yet) would be to convert (ordered) factors into a pair of dummy variables. If the (ordered) factors have missing values, the dummy variables could be included as columns of Y and imputed, but then you have to decide how to convert the continuously distributed imputed values for these dummy codes back into categories.

Note on not full row-rank

If the restriction matrix is not of full row-rank, this means one of the following:

- There is at least one redundant restriction specified in the hypothesis. Then, either
 - [a] Leave the redundant one out
 - [b] Use another (more time-consuming) way of obtaining the level probabilities for the penalty term (`goric` function does this by default): Bootstrapping, as discussed above.

- There is at least one range restriction (e.g., $-2 < \text{group1} < 2$). Such a restriction can be evaluated but there is a sensitivity (of a scaling factor in the covariance matrix, like with a prior in a Bayes factor) which currently cannot be checked for.
- There is at least one conflicting restriction (e.g., $2 < \text{group1} < -2$).

Such a restriction can evidently never hold and is thus impossible to evaluate. To prevent this type of error delete the one that is incorrect.

Value

The function returns a dataframe with the log-likelihood, penalty term, GORIC(A) values and the GORIC(A) weights. Furthermore, a dataframe is returned with the relative GORIC(A) weights.

Examples

```
## By following these examples, you can appropriately specify hypotheses based on
## your research questions and analytical framework.

# The hypotheses (i.e., constraints) have to be in a list. It is recommended to name
# each hypothesis in the list. Otherwise the hypotheses are named accordingly 'H1', 'H2', \dots.
# Another option is to use the \code{l1list()} function from the \pkg{Hmisc} package, where.

# text-based syntax (the labels x1, x2, and x3 are the names of coef(model) or names(vector))
h1 <- '(x1, x2, x3) > 0'
h2 <- '(x1, x3) > 0; x2 = 0'
h3 <- 'x1 > 0; x2 < 0; x3 = 0'
hypotheses = list(hypo1 = h1, hypo2 = h2, hypo3 = h3)

# define constraints matrix directly (note that the constraints have to be specified pairwise).
# the element names (i.e., constraints, rhs, neq) must be used.
h1 <- list(constraints = c(0,1,0))
h2 <- list(constraints = rbind(c(0,1,0), c(0,0,1)), rhs = c(0.5, 1), neq = 0)
hypotheses = list(H1 = h1, H2 = h2)

# mixed syntax:
hypotheses = list(Ha = h1, Hb = 'x1 = x2 > x3')
```

```

# lavaan object syntax:
# the recommended option for objects of class lavaan is to use labels (here a, b and c)
# to define our hypothesis.
model.lav <- "y ~ 1 + a*x1 + b*x2 + c*x3 + x4"
# fit lavaan model, for example
# library(lavaan)
# fit.lav <- sem(model, data = DATA)
# define hypothesis syntax
hypotheses = list(h1 = 'a > b > c')
# if needed absolute values can be used.
hypotheses = list(h1 = 'abs(a) > abs(b) > abs(c)')

Hurricanes

The Hurricanes Dataset

Description

The data provide information on the effect of El Nino (Cold, Neutral, Warm) on the number of hurricanes from 1950 to 1995.

Usage

```
data(Hurricanes)
```

Format

A data frame of 46 observations of 3 variables.

Year

Hurricanes Number of Hurricanes

ElNino 1=Cold, 2=Neutral, 3=Warm

References

The original source of these data is the National Hurricane Center in Australia. The dataset was extracted from the table on page 5 in Silvapulle and Sen (2005).

Examples

```
head(Hurricanes)
```

         parallel = c("no", "multicore", "snow"),
         ncpus = 1L, cl = NULL, verbose = FALSE, ...)
```

Arguments

object	<p>an object of class <code>lm</code> or <code>r1m</code>. In this case, the constraint syntax needs to be specified</p> <p>OR</p> <p>an object of class <code>restriktor</code>. The constraints are inherited from the fitted <code>restriktor</code> object and do not to be specified again.</p>
model	lavaan model syntax specifying the model. See model.syntax for more information.
constraints	<p>there are two ways to constrain parameters. First, the constraint syntax consists of one or more text-based descriptions, where the syntax can be specified as a literal string enclosed by single quotes. Only the names of <code>coef(model)</code> can be used as names. See details restriktor for more information.</p> <p>Second, the constraint syntax consists of a matrix R (or a vector in case of one constraint) and defines the left-hand side of the constraint $R\theta \geq rhs$, where each row represents one constraint. The number of columns needs to correspond to the number of parameters estimated (θ) by model. The rows should be linear independent, otherwise the function gives an error. For more information about constructing the matrix R and rhs see the details in the restriktor function.</p>
data	the data frame containing the observed variables being used to fit the lavaan model.
type	hypothesis test type "A", "B", "C", "global", or "summary" (default). See details for more information.

test	<p>test statistic; for information about the null-distribution see details.</p> <ul style="list-style-type: none"> • for object of class <code>lm</code>; if "F" (default), the F-bar statistic (Silvapulle, 1996) is computed. If "LRT", a likelihood ratio test statistic (Silvapulle and Sen, 2005, chp 3.) is computed. If "score", a global score test statistic (Silvapulle and Silvapulle, 1995) is computed. Note that, in case of equality constraints only, the usual unconstrained F-, Wald-, LR- and score-test statistic is computed. • for object of class <code>rlm</code>; if "F" (default), a robust likelihood ratio type test statistic (Silvapulle, 1992a) is computed. If "Wald", a robust Wald test statistic (Silvapulle, 1992b) is computed. If "score", a global score test statistic (Silvapulle, and Silvapulle, 1995) is computed. Note that, in case of equality constraints only, unconstrained robust F-, Wald-, score-test statistics are computed. • for object of class <code>glm</code>; if "F" (default), the F-bar statistic (Silvapulle, 1996) is computed. If "LRT", a likelihood ratio test statistic (Silvapulle and Sen, 2005, chp 4.) is computed. If "score", a global score test statistic (Silvapulle and Silvapulle, 1995) is computed. Note that, in case of equality constraints only, the usual unconstrained F-, Wald-, LR- and score-test statistic is computed.
rhs	vector on the right-hand side of the constraints; $R\theta \geq rhs$. The length of this vector equals the number of rows of the constraints matrix R and consists of zeros by default. Note: only used if constraints input is a matrix or vector.
neq	integer (default = 0) treating the number of constraints rows as equality constraints instead of inequality constraints. For example, if <code>neq = 2</code> , this means that the first two rows of the constraints matrix R are treated as equality constraints. Note: only used if constraints input is a matrix or vector.
neq.alt	integer: number of equality constraints that are maintained under the alternative hypothesis (for hypothesis test type "B").
R	Integer; number of bootstrap draws. The default value is set to 1000.
bootstrap.type	If "parametric", the parametric bootstrap is used. If "bollen.stine", the semi-nonparametric Bollen-Stine bootstrap is used. The default is set to "bollen.stine".
return.test	Logical; if TRUE, the function returns bootstrapped test-values.
double.bootstrap	If "standard" (default) the genuine double bootstrap is used to compute an additional set of plug-in p-values for each bootstrap sample. If "no", no double bootstrap is used. If "FDB", the fast double bootstrap is used to compute second level LRT-values for each bootstrap sample. Note that the "FDB" is experimental and should not be used by inexperienced users.
double.bootstrap.R	Integer; number of double bootstrap draws. The default value is set to 249.
double.bootstrap.alpha	The significance level to compute the adjusted alpha based on the plugin p-values. Only used if <code>double.bootstrap = "standard"</code> . The default value is set to 0.05.
parallel	The type of parallel operation to be used (if any). If missing, the default is set "no".

<code>ncpus</code>	Integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
<code>cl</code>	An optional parallel or snow cluster for use if <code>parallel = "snow"</code> . If not supplied, a cluster on the local machine is created for the duration of the <code>InformativeTesting</code> call.
<code>verbose</code>	Logical; if TRUE, information is shown at each bootstrap draw.
<code>...</code>	further options for the <code>iht</code> and/or <code>restriktor</code> function. See details for more information.

Details

The following hypothesis tests are available:

- Type A: Test H0: all constraints with equalities ("=") active against HA: at least one inequality restriction(">") strictly true.
- Type B: Test H0: all constraints with inequalities(">") (including some equalities("=")) active against HA: at least one restriction false (some equality constraints may be maintained).
- Type C: Test H0: at least one restriction false("<") against HA: all constraints strikty true(">"). This test is based on the intersection-union principle (Silvapulle and Sen, 2005, chp 5.3). Note that, this test only makes sense in case of no equality constraints.
- Type global: equal to Type A but H0 contains additional equality constraints. This test is analogue to the global F-test in `lm`, where all coefficients but the intercept equal 0.

The null-distribution of hypothesis test Type C is based on a t-distribution (one-sided). Its power can be poor in case of many inequality constraints. Its main role is to prevent wrong conclusions from significant results from hypothesis test Type A.

The exact finite sample distributions of the non-robust F-, score- and LR-test statistics based on restricted OLS estimates and normally distributed errors, are a mixture of F-distributions under the null hypothesis (Wolak, 1987). For the robust tests, we found that the results based on these mixtures of F-distributions approximate the tail probabilities better than their asymptotic distributions.

Note that, in case of equality constraints only, the null-distribution of the (non-)robust F-test statistics are based on an F-distribution. The (non-)robust Wald- and (non-)robust score-test statistics are based on chi-square distributions.

If object is of class `lm` or `r1m`, the `conTest` function internally calls the `restriktor` function. Arguments for the `restriktor` function can be passed on via the `...`. Additional arguments for the `conTest` function can also passed on via the `...`. See for example `conTestF` for all available arguments.

Value

An object of class `conTest` or `conTestLavaan` for which a print is available.

 iht-methods

Methods for iht

Description

Print function for objects of class conTest.

Usage

```
## S3 method for class 'conTest'
print(x, digits = max(3, getOption("digits") - 2), ...)
```

Arguments

x	an object of class conTest.
digits	the number of significant digits to use when printing.
...	no additional arguments for now.

Value

No return value, just the result of the print function

Examples

```

# unrestricted linear model for ages (in months) at which an
# infant starts to walk alone.

# prepare data
DATA <- subset(ZelazoKolb1972, Group != "Control")

# fit unrestricted linear model
fit.lm <- lm(Age ~ -1 + Group, data = DATA)

# restricted linear model with restrictions that the walking
# exercises would not have a negative effect of increasing the
# mean age at which a child starts to walk.
fit.con <- restriktor(fit.lm, constraints = "GroupActive < GroupPassive < GroupNo")

iht(fit.con)

```

myGORICs

An example of IC values

Description

An example of IC: A matrix with information criteria (AIC, ORIC, GORIC, or GORICA) values of size 4×3 (in general: $S \times \text{'NrHypo}+1\text{'}$, where $\text{'NrHypo}+1\text{'}$ stands for the number of theory-based hypotheses plus a safeguard hypothesis (the complement or unconstrained)).

Usage

```
data(myGORICs)
```

Format

An object of class `matrix` (inherits from `array`) with 4 rows and 3 columns.

Examples

```
data(myGORICs)
```

`myLLs`*An example of log-likelihood (LL) values*

Description

An example of LL: A matrix with log-likelihood values of size 4 x 3 (in general: S x 'NrHypos+1', where 'NrHypos+1' stands for the number of theory-based hypotheses plus a safeguard hypothesis (the complement or unconstrained)).

Usage

```
data(myLLs)
```

Format

An object of class `matrix` (inherits from `array`) with 4 rows and 3 columns.

Examples

```
data(myLLs)
```

`myPTs`*An example of penalty (PT) values*

Description

An example of PT: A matrix with penalty values of size 4 x 3 (in general: S x 'NrHypos+1', where 'NrHypos+1' stands for the number of theory-based hypotheses plus a safeguard hypothesis (the complement or unconstrained)).

Usage

```
data(myPTs)
```

Format

An object of class `matrix` (inherits from `array`) with 4 rows and 3 columns.

Examples

```
data(myPTs)
```

Description

Function `restriktor` estimates the parameters of an univariate and a multivariate linear model (`lm`), a robust estimation of the linear model (`rlm`) and a generalized linear model (`glm`) subject to linear equality and linear inequality restrictions. It is a convenience function. The real work horses are the `conLM`, `conMLM`, `conRLM` and the `conGLM` functions.

Usage

```
restriktor(object, constraints = NULL, ...)
```

```
## S3 method for class 'lm'
```

```
conLM(object, constraints = NULL, se = "standard",
      B = 999, rhs = NULL, neq = 0L, mix_weights = "pmvnorm",
      parallel = "no", ncpus = 1L, cl = NULL, seed = NULL,
      control = list(), verbose = FALSE, debug = FALSE, ...)
```

```
## S3 method for class 'rlm'
```

```
conRLM(object, constraints = NULL, se = "standard",
      B = 999, rhs = NULL, neq = 0L, mix_weights = "pmvnorm",
      parallel = "no", ncpus = 1L, cl = NULL, seed = NULL,
      control = list(), verbose = FALSE, debug = FALSE, ...)
```

```
## S3 method for class 'glm'
```

```
conGLM(object, constraints = NULL, se = "standard",
      B = 999, rhs = NULL, neq = 0L, mix_weights = "pmvnorm",
      parallel = "no", ncpus = 1L, cl = NULL, seed = NULL,
      control = list(), verbose = FALSE, debug = FALSE, ...)
```

```
## S3 method for class 'mlm'
```

```
conMLM(object, constraints = NULL, se = "none",
      B = 999, rhs = NULL, neq = 0L, mix_weights = "pmvnorm",
      parallel = "no", ncpus = 1L, cl = NULL, seed = NULL,
      control = list(), verbose = FALSE, debug = FALSE, ...)
```

Arguments

- | | |
|--------------------------|--|
| <code>object</code> | a fitted linear model object of class " <code>lm</code> ", " <code>mlm</code> ", " <code>rlm</code> " or " <code>glm</code> ". For class " <code>rlm</code> " only the loss function bisquare is supported for now, otherwise the function gives an error. |
| <code>constraints</code> | there are two ways to constrain parameters. First, the constraint syntax consists of one or more text-based descriptions, where the syntax can be specified as a literal string enclosed by single quotes. Only the names of <code>coef(model)</code> can |

be used as names. See details for more information. Note that objects of class "mlm" do not (yet) support this method.

Second, the constraint syntax consists of a matrix R (or a vector in case of one constraint) and defines the left-hand side of the constraint $R\theta \geq rhs$, where each row represents one constraint. The number of columns needs to correspond to the number of parameters estimated (θ) by model. The rows should be linear independent, otherwise the function gives an error. For more information about constructing the matrix R and rhs see details.

se	if "standard" (default), conventional standard errors are computed based on inverting the observed augmented information matrix. If "const", homoskedastic standard errors are computed. If "HC0" or just "HC", heteroskedastic robust standard errors are computed (a.k.a Huber White). The options "HC1", "HC2", "HC3", "HC4", "HC4m", and "HC5" are refinements of "HC0". For more details about heteroskedastic robust standard errors see the sandwich package. If "boot.standard", bootstrapped standard errors are computed using standard bootstrapping. If "boot.model.based" or "boot.residual", bootstrapped standard errors are computed using model-based bootstrapping. If "none", no standard errors are computed. Note that for objects of class "mlm" no standard errors are available (yet).
B	integer; number of bootstrap draws for se. The default value is set to 999. Parallel support is available.
rhs	vector on the right-hand side of the constraints; $R\theta \geq rhs$. The length of this vector equals the number of rows of the constraints matrix R and consists of zeros by default. Note: only used if constraints input is a matrix or vector.
neq	integer (default = 0) treating the number of constraints rows as equality constraints instead of inequality constraints. For example, if neq = 2, this means that the first two rows of the constraints matrix R are treated as equality constraints. Note: only used if constraints input is a matrix or vector.
mix_weights	if "pmvnorm" (default), the chi-bar-square weights are computed based on the multivariate normal distribution function with additional Monte Carlo steps. If "boot", the chi-bar-square weights are computed using parametric bootstrapping. If "none", no chi-bar-square weights are computed. The weights are necessary in the <code>restriktor.summary</code> function for computing the GORIC. Moreover, the weights are re-used in the <code>ihf</code> function for computing the p-value for the test-statistic, unless the p-value is computed directly via bootstrapping.
parallel	the type of parallel operation to be used (if any). If missing, the default is set "no".
ncpus	integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
cl	an optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the <code>restriktor</code> call.
seed	seed value.
control	a list of control arguments: <ul style="list-style-type: none"> • <code>absval</code> tolerance criterion for convergence (default = <code>sqrt(.Machine\$double.eps)</code>). • <code>maxit</code> the maximum number of iterations for the optimizer (default = 10000).

- `tol` numerical tolerance value. Estimates smaller than `tol` are set to 0.

Control options for calculating the chi-bar-square weights:

- `chunk_size` integer; the chi-bar-square weights are computed for samples of size `chunk_size = 5000L`. This process is repeated iteratively until the weights converges (see `convergence_crit`) or the maximum is reached, i.e., `mix_weights_bootstrap_limit`.
- `mix_weights_bootstrap_limit` integer; maximum number of bootstrap draws. The default value is set to `1e5`.
- `convergence_crit` the convergence criterion for the iterative bootstrap process. Default is `1e-03`.

`verbose` logical; if TRUE, information is shown at each bootstrap draw.

`debug` if TRUE, debugging information about the constraints is printed out.

Options for calculating the chi-bar-square weights:

... parameters passed to the truncated multivariate normal distribution. By default, `restriktor` (i.e. `con_weights_boot` function) uses no truncation points for calculating the chi-bar-square weights, which renders to the multivariate normal distribution. See the manual page of the `rtmvnorm` function from the **rtmvnorm** to see how to specify a truncated mvnorm distribution and the possible arguments.

Details

The constraint syntax can be specified in two ways. First as a literal string enclosed by single quotes as shown below:

```
myConstraints <- '
# 1. inequality constraints
  x1 > 0
  x1 < x2
# or
  0 < x1 < x2

! 2. equality constraints
  x3 == x4; x4 == x5
# or
  x3 = x4; x4 = x5
# or
  x3 = x4 = x5'
```

The variable names `x1` to `x5` refer to the corresponding regression coefficient. Thus, constraints are imposed on regression coefficients and not on the data.

Second, the above constraints syntax can also be written in matrix/vector notation as:

(The first column refers to the intercept, the remaining five columns refer to the regression coefficients `x1` to `x5`.)

```

myConstraints <-
  rbind(c(0, 0, 0,-1, 1, 0), #equality constraint x3 = x4
        c(0, 0, 0, 0,-1, 1), #equality constraint x4 = x5
        c(0, 1, 0, 0, 0, 0), #inequality constraint x1 > rhs
        c(0,-1, 1, 0, 0, 0)) #inequality constraint x1 < x2

# the length of rhs is equal to the number of myConstraints rows.
myRhs <- c(0,0,0,0)

# the first two rows should be considered as equality constraints
myNeq <- 2

```

Blank lines and comments can be used in between the constraints, and constraints can be split over multiple lines. Both the hashtag (#) and the exclamation (!) characters can be used to start a comment. Multiple constraints can be placed on a single line if they are separated by a semicolon (;), a comma (,) or the "&" sign.

In addition compound constraints can be stated via one or more longer equality or inequality sentences e.g., 'x1 > x2 > x3; x3 < 4 < x4' or 'x1 == x2 == x3 & x4 = 1'. Alternatively, the constraints can be specified as '(x1, x2) > (x3, x4)' which is equivalent to 'x1 > x3; x1 > x4; x2 > x3; x2 > x4'.

There can be three types of text-based descriptions in the constraints syntax:

1. Equality constraints: The "==" or "=" operator can be used to define equality constraints (e.g., x1 = 1 or x1 = x2).
2. Inequality constraints: The "<" or ">" operator can be used to define inequality constraints (e.g., x1 > 1 or x1 < x2).
3. Newly defined parameters: The ":=" operator can be used to define new parameters, which take on values that are an arbitrary function of the original model parameters. The function must be specified in terms of the parameter names in `coef(model)` (e.g., new := x1 + 2*x2). By default, the standard errors for these defined parameters are computed by using the so-called Delta method.

Variable names of interaction effects in objects of class `lm`, `rlm` and `glm` contain a semi-colon (;) between the variables. To impose constraints on parameters of interaction effects, the semi-colon must be replaced by a dot (.) (e.g., x3:x4 becomes x3.x4). In addition, the intercept variable names is shown as "(Intercept)". To impose restrictions on the intercept both parentheses must be replaced by a dot ". Intercept." (e.g., Intercept. > 10). Note: in most practical situations we do not impose restrictions on the intercept because we do not have prior knowledge about the intercept. Moreover, the sign of the intercept can be changed arbitrarily by shifting the response variable y .

Each element can be modified using arithmetic operators. For example, if x2 is expected to be twice as large as x1, then "2*x2 = x1".

If `constraints = NULL`, the unrestricted model is fitted.

Note on not full row-rank

If the restriction matrix is not of full row-rank, this means one of the following:

- There is at least one redundant restriction. Then, either
 - [a] Leave the redundant one out

- [b] Use another (more time-consuming) way of obtaining the level probabilities for the penalty term (goric function does this by default): Bootstrapping, as discussed above.
- There is at least one range restriction (e.g., $-2 < \text{group1} < 2$). Such a restriction can be evaluated but there is a sensitivity (of a scaling factor in the covariance matrix, like with a prior in a Bayes factor) which currently cannot be checked for.
- There is at least one conflicting restriction (e.g., $2 < \text{group1} < -2$).

Such a restriction can evidently never hold and is thus impossible to evaluate. To prevent this type of error delete the one that is incorrect.

Value

An object of class `restriktor`, for which a `print` and a `summary` method are available. More specifically, it is a list with the following items:

<code>CON</code>	a list with useful information about the restrictions.
<code>call</code>	the matched call.
<code>timing</code>	how much time several tasks take.
<code>parTable</code>	a parameter table with information about the observed variables in the model and the imposed restrictions.
<code>b.unrestr</code>	unrestricted regression coefficients.
<code>b.restr</code>	restricted regression coefficients.
<code>residuals</code>	restricted residuals.
<code>wresid</code>	a working residual, weighted for "inv.var" weights only (rlm only)
<code>fitted</code>	restricted fitted mean values.
<code>weights</code>	(only for weighted fits) the specified weights.
<code>wgt</code>	the weights used in the IWLS process (rlm only).
<code>scale</code>	the robust scale estimate used (rlm only).
<code>stddev</code>	a scale estimate used for the standard errors.
<code>R2.org</code>	unrestricted R-squared.
<code>R2.reduced</code>	restricted R-squared.
<code>df.residual</code>	the residual degrees of freedom
<code>s2.unrestr</code>	mean squared error of unrestricted model.
<code>s2.restr</code>	mean squared error of restricted model.
<code>loglik</code>	restricted log-likelihood.
<code>Sigma</code>	variance-covariance matrix of unrestricted model.
<code>constraints</code>	matrix with restrictions.
<code>rhs</code>	vector of right-hand side elements.
<code>neq</code>	number of equality restrictions.
<code>wt.bar</code>	chi-bar-square mixing weights or a.k.a. level probabilities.
<code>iact</code>	active restrictions.

converged	did the IWLS converge (rlm only)?
iter	number of iteration needed for convergence (rlm only).
bootout	object of class boot. Only available if bootstrapped standard errors are requested, else bootout = NULL.
control	list with control options.
model.org	original model.
se	as input. This information is needed in the summary function.
information	observed information matrix with the inverted information matrix and the augmented information matrix as attributes.

```

Description

restricted estimation and confidence intervals for (robust) linear (in)equality restricted hypotheses.

Usage

```
## S3 method for class 'restriktor'
print(x, digits = max(3, getOption("digits") - 2), ...)

## S3 method for class 'restriktor'
summary(object, bootCIs = TRUE,
         bty = "perc", level = 0.95, goric = "goric", ...)

## S3 method for class 'summary.restriktor'
print(x, digits = max(3, getOption("digits") - 2),
      signif.stars = getOption("show.signif.stars"), ...)

## S3 method for class 'restriktor'
coef(object, ...)

## S3 method for class 'restriktor'
model.matrix(object, ...)

## S3 method for class 'restriktor'
logLik(object, ...)
```

Arguments

object	an object of class restriktor.
x	an object of class restriktor.
bootCIs	if TRUE (default), nonparametric bootstrap confidence intervals are generated. Only available if object contains bootout object.
bty	a character string representing the type of interval required. The value should be any of the values "norm", "basic", "perc", "bca". The value "stud" is not supported. For more details see boot.ci .
level	the confidence level of the interval (default = 0.95).
goric	if "goric" (default), the generalized order-restricted information criterion value is computed. If "gorica" the log-likelihood is computed using the multivariate normal distribution function. If "goricc" or "goricca", a small sample version of the "goric" or "gorica" is computed.

<code>digits</code>	the number of significant digits to use when printing.
<code>signif.stars</code>	If TRUE, "significance stars are printed for each coefficient.
<code>...</code>	no additional arguments for now.

Details

The function `print` returns the restricted coefficients. The output from the `print.summary.conLM` function provides information that is comparable with the output from `print.summary.lm`. Additional information is provided about the unrestricted and restricted R-square and by default the output of the GORIC. If bootstrapped standard errors are requested (e.g., option `se = "boot.model.based"` in the `restriktor` function and `bootCI = TRUE` in the summary function) standard errors and confidence intervals are provided.

Value

The function `summary` computes and returns a list of summary statistics of the fitted unrestricted and restricted (robust) linear model given in `object`, plus

<code>se.type</code>	type of standard error computed, equal to input <code>se</code> in the <code>restriktor</code> function.
<code>residuals</code>	the weighted residuals.
<code>coefficients</code>	a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding p-value. If <code>bootCIs = TRUE</code> and the <code>bootout</code> object is available in the object, bootstrapped standard errors and confidence intervals are produced.
<code>rdf</code>	residual degrees of freedom.
<code>R2.org</code>	unrestricted R-squared.
<code>R2.reduced</code>	restricted R-squared.
<code>goric</code>	goric value and attributed its penalty term and log-likelihood.

Examples

```
# unrestricted linear model for ages (in months) at which an
# infant starts to walk alone.

# prepare data
DATA <- subset(ZelazoKolb1972, Group != "Control")

# fit unrestricted linear model
fit.lm <- lm(Age ~ -1 + Group, data = DATA)

# restricted linear model with restrictions that the walking
# exercises would not have a negative effect of increasing the
# mean age at which a child starts to walk.
fit.con <- restriktor(fit.lm, constraints = ' GroupActive < GroupPassive < GroupNo ')

summary(fit.con)
```

ZelazoKolb1972 *"Walking" in the newborn (4 treatment groups)*

Description

The Zelazo, Zelazo and Kolb (1972) dataset consists of ages (in months) at which an infant starts to walk alone from four different treatment groups (Active-exercise, Passive-exercise, 8 week Control, No-exercise).

Usage

```
data(ZelazoKolb1972)
```

Format

A data frame of 23 observations of 4 treatment variables.

Age Age in months

Group Active-exercise, Passive-exercise, 8-week Control group, No-exercise
